

Lecture 2: 2D Fourier transforms and applications

B14 Image Analysis

Michaelmas 2014

A. Zisserman

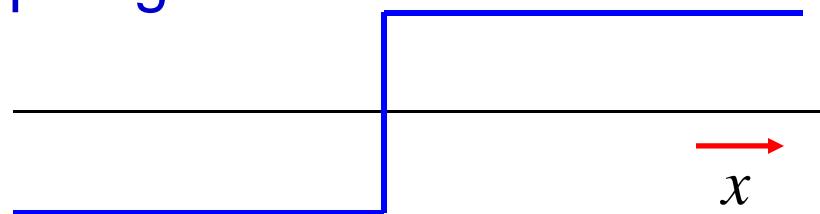

- Fourier transforms and spatial frequencies in 2D
 - Definition and meaning
- The Convolution Theorem
 - Applications to spatial filtering
- The Sampling Theorem and Aliasing

Much of this material is a straightforward generalization of the 1D Fourier analysis with which you are familiar.

Reminder: 1D Fourier Series

Spatial frequency analysis of a step edge

$$f(x) = \begin{cases} -1 & \text{if } x < 0 \\ 1 & \text{otherwise} \end{cases}$$

Fourier decomposition

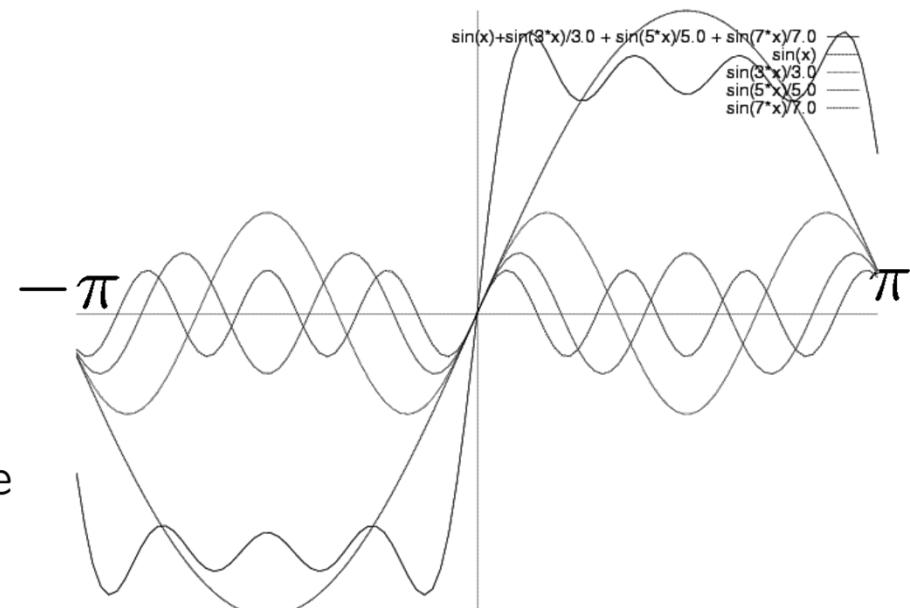

Fourier Series

$$f(x) = \sum_n a_n \sin nx$$

$$a_n = \frac{1}{\pi} \int_{-\pi}^{\pi} f(x) \sin nx dx$$

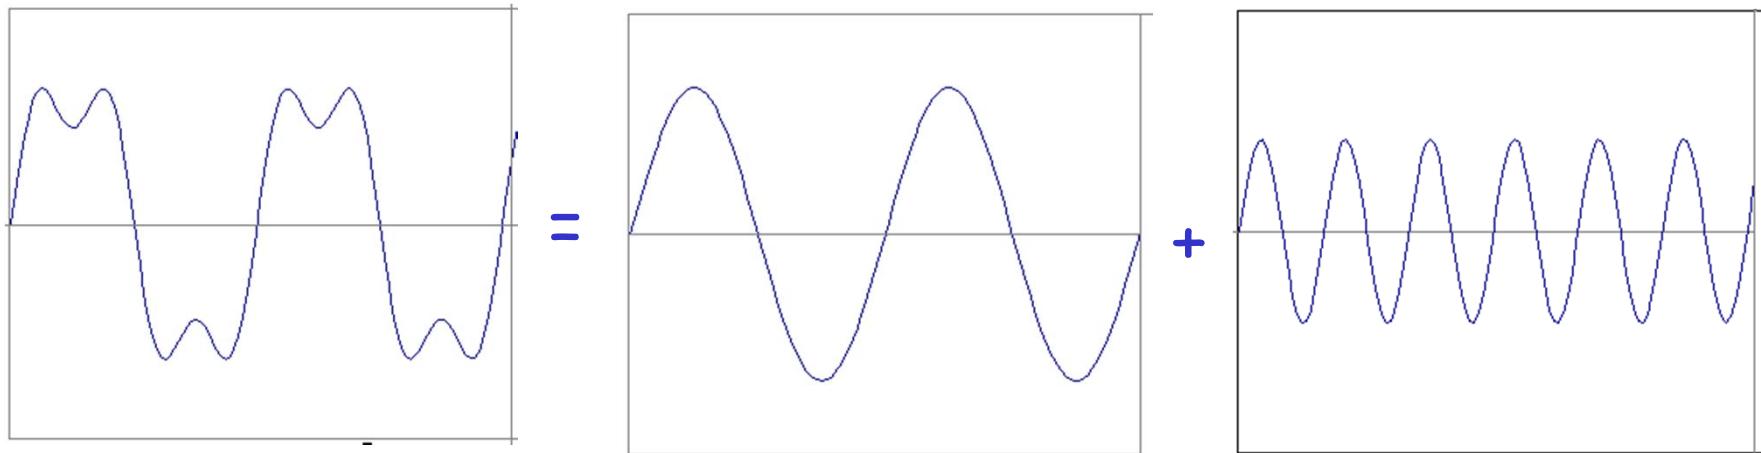

$$= \frac{2}{\pi} \int_0^{\pi} \sin nx dx = \begin{cases} \frac{4}{n\pi} & \text{if } n \text{ odd} \\ 0 & \text{otherwise} \end{cases}$$

$$f(x) = \sum_{n=1}^{\infty} \frac{4}{(2n-1)\pi} \sin((2n-1)x)$$

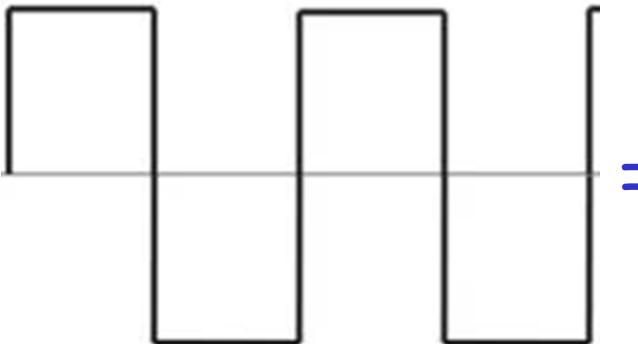

Fourier series remainder

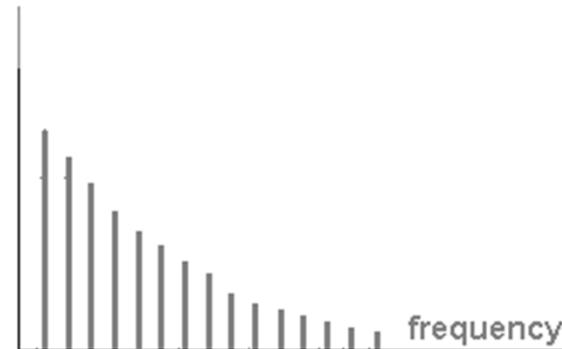

Example

$$f(x) = \sin x + \frac{1}{3} \sin 3x + \dots$$

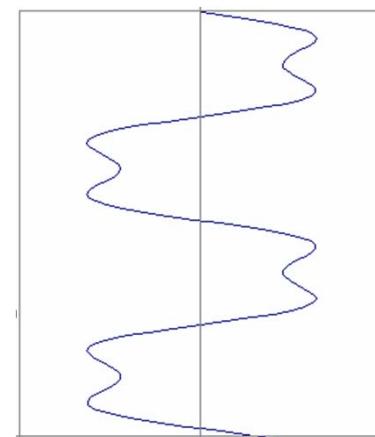

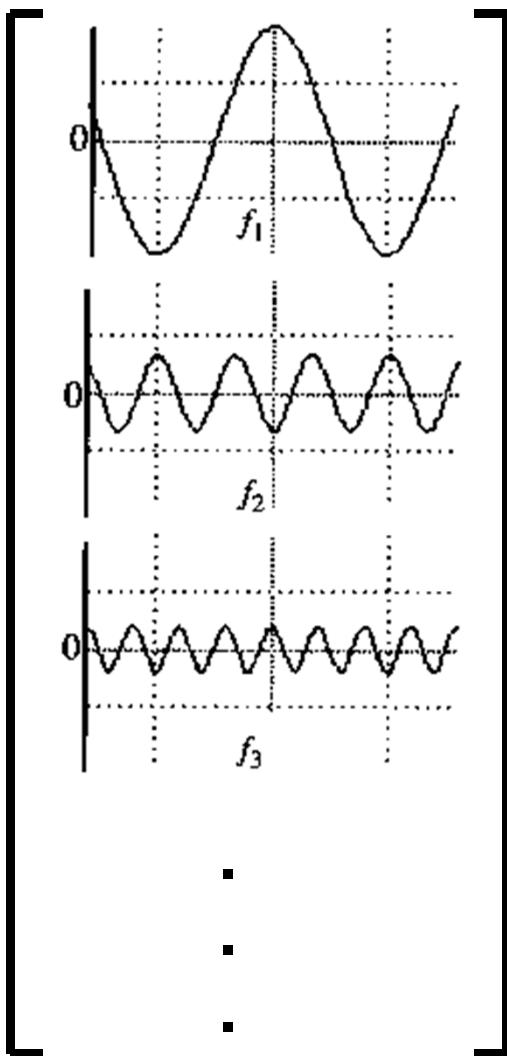

Fourier series for a square wave

$$f(x) = \sum_{n=1,3,5,\dots} \frac{1}{n} \sin nx$$

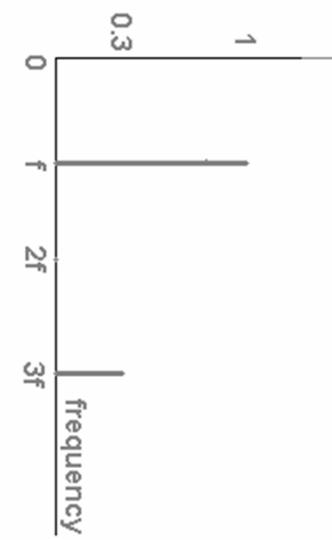

Fourier series: just a change of basis

$$\text{M } f(x) = F(\omega)$$

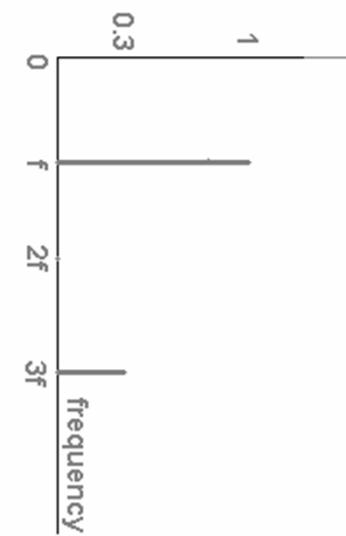

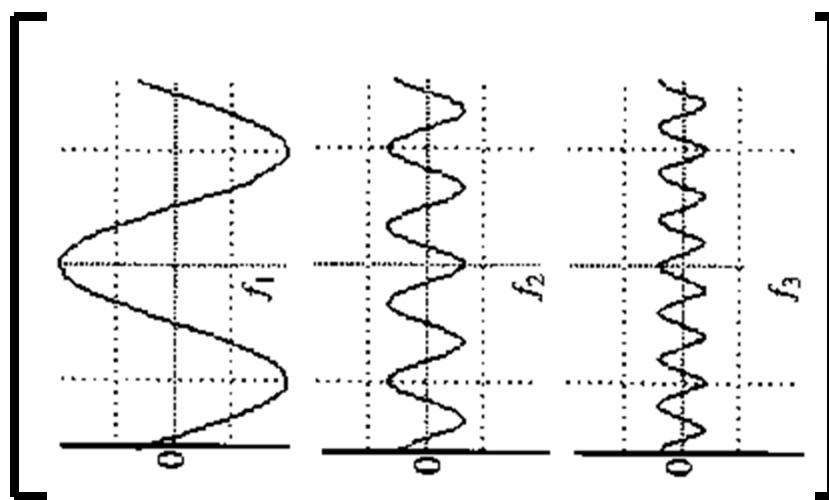

=

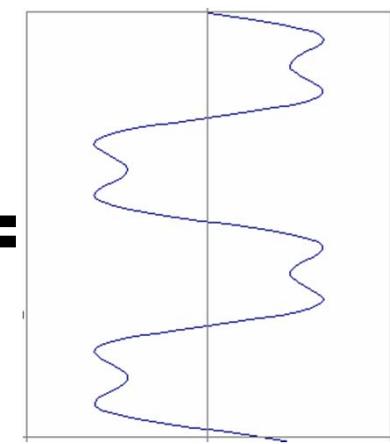

Inverse FT: Just a change of basis

$$M^{-1} F(\omega) = f(x)$$

=

1D Fourier Transform

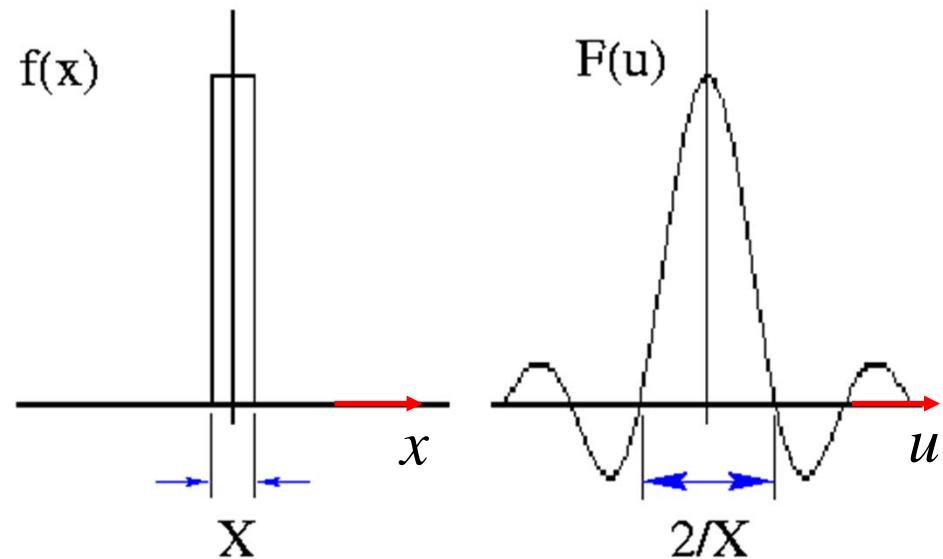

Reminder transform pair - definition

$$F(u) = \int_{-\infty}^{\infty} f(x) e^{-j2\pi ux} dx,$$
$$f(x) = \int_{-\infty}^{\infty} F(u) e^{j2\pi ux} du$$

Example

$$f(x) = \begin{cases} 1, & |x| < \frac{X}{2}, \\ 0, & |x| \geq \frac{X}{2}. \end{cases}$$

$$\begin{aligned} F(u) &= \int_{-\infty}^{\infty} f(x) e^{-j2\pi ux} dx \\ &= \int_{-X/2}^{X/2} e^{-j2\pi ux} dx \\ &= \frac{1}{-j2\pi u} [e^{-j2\pi uX/2} - e^{j2\pi uX/2}] \\ &= X \frac{\sin(\pi Xu)}{(\pi Xu)} = X \text{sinc}(\pi Xu). \end{aligned}$$

2D Fourier transforms

2D Fourier transform

Definition

$$F(u, v) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x, y) e^{-j2\pi(ux+vy)} dx dy,$$
$$f(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F(u, v) e^{j2\pi(ux+vy)} du dv$$

where u and v are spatial frequencies.

Also will write FT pairs as $f(x, y) \Leftrightarrow F(u, v)$.

- $F(u, v)$ is complex in general,

$$F(u, v) = F_R(u, v) + jF_I(u, v)$$

- $|F(u, v)|$ is the **magnitude** spectrum
- $\arctan(F_I(u, v)/F_R(u, v))$ is the **phase** angle spectrum.
- Conjugacy: $f^*(x, y) \Leftrightarrow F(-u, -v)$
- Symmetry: $f(x, y)$ is **even** if $f(x, y) = f(-x, -y)$

Sinusoidal Waves

In 1D the Fourier transform is based on a decomposition into functions $e^{j2\pi ux} = \cos 2\pi ux + j \sin 2\pi ux$ which form an orthogonal basis. Similarly in 2D

$$e^{j2\pi(ux+vy)} = \cos 2\pi(ux + vy) + j \sin 2\pi(ux + vy)$$

The real and imaginary terms are sinusoids on the x, y plane. The maxima and minima of $\cos 2\pi(ux + vy)$ occur when

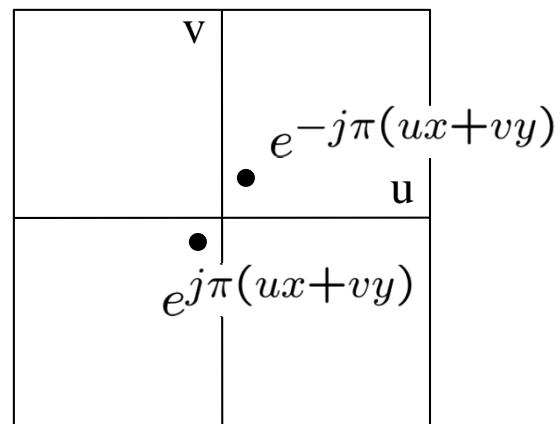

$$2\pi(ux + vy) = n\pi$$

write $ux + vy$ using vector notation with $\mathbf{u} = (u, v)^\top$, $\mathbf{x} = (x, y)^\top$ then

$$2\pi(ux + vy) = 2\pi\mathbf{u} \cdot \mathbf{x} = n\pi$$

are sets of equally spaced parallel lines with normal \mathbf{u} and wavelength $1/\sqrt{u^2 + v^2}$.

To get some sense of what basis elements look like, we plot a basis element --- or rather, its real part --- as a function of x, y for some fixed u, v . We get a function that is constant when $(ux+vy)$ is constant. The magnitude of the vector (u, v) gives a frequency, and its direction gives an orientation. The function is a sinusoid with this frequency along the direction, and constant perpendicular to the direction.

Here u and v are larger than
in the previous slide.

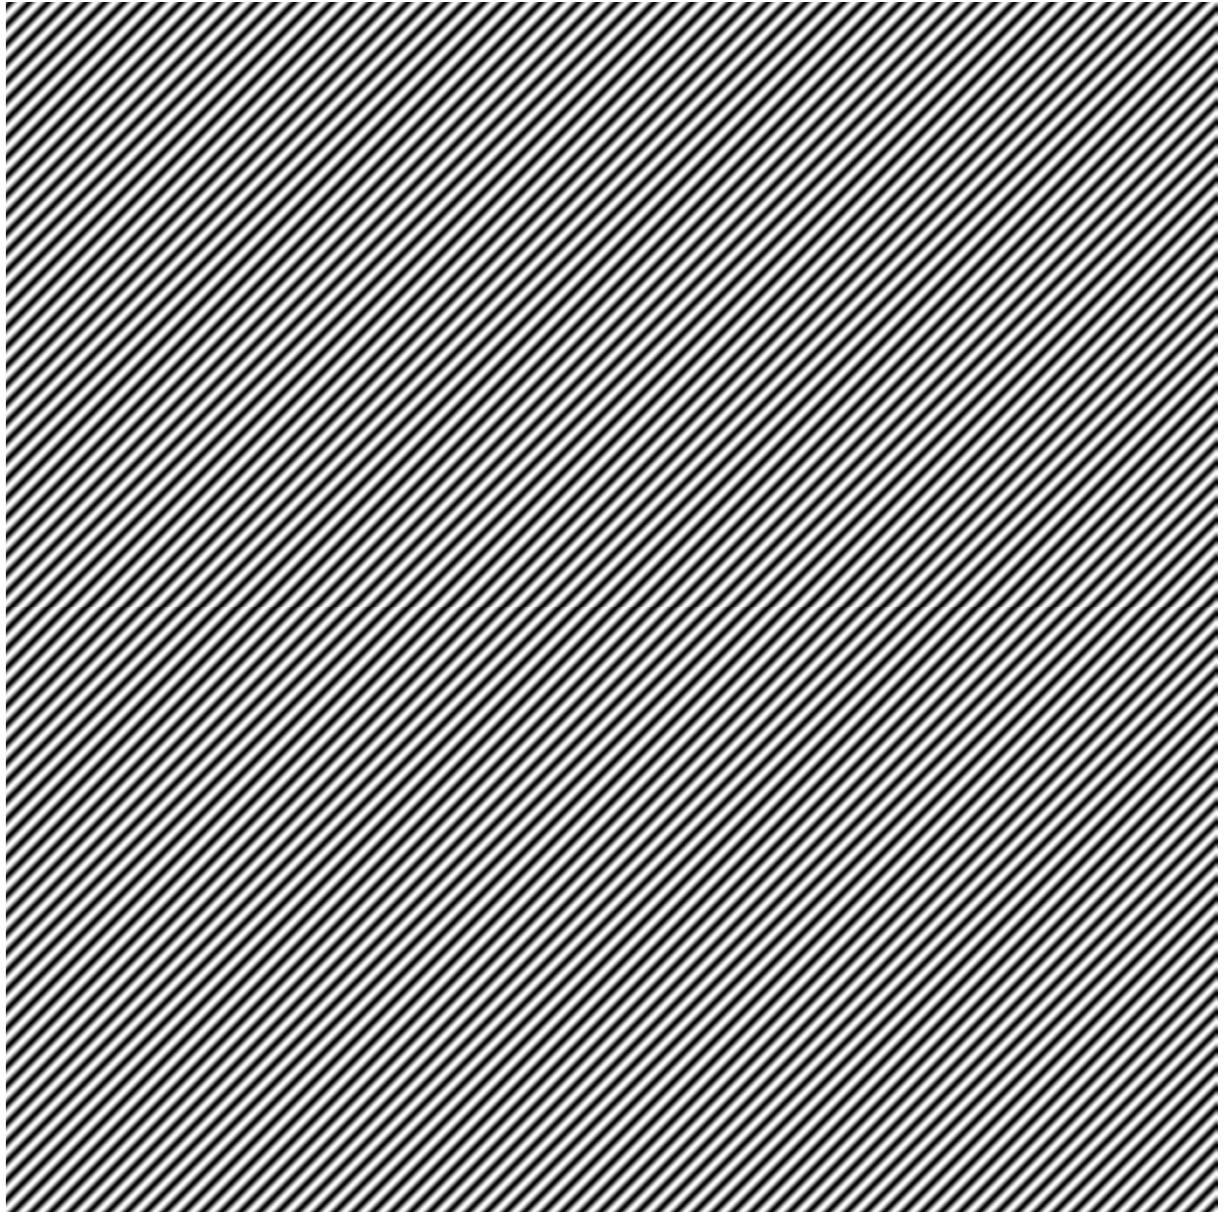

| | |
|--------------------|-------------------|
| | v |
| $e^{-j\pi(ux+vy)}$ | • |
| • | u |
| | $e^{j\pi(ux+vy)}$ |

And larger still...

$$e^{-j\pi(ux+vy)}$$

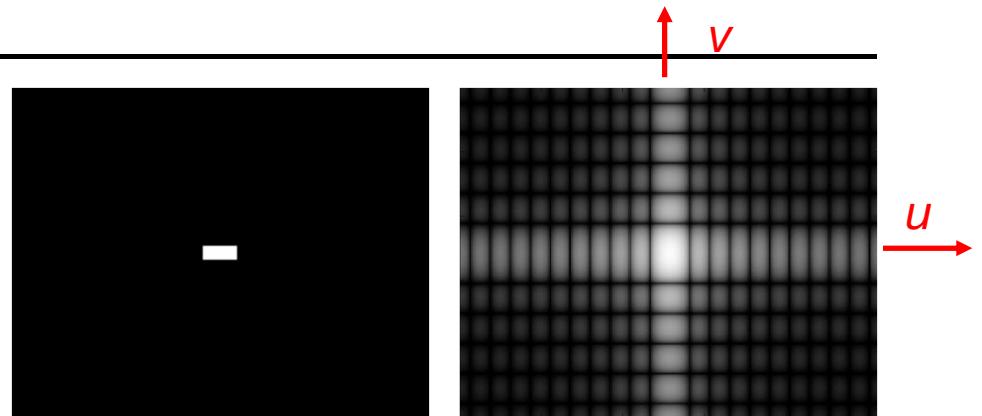

| | | |
|---|---|------------------------|
| • | v | |
| | | u |
| | | $e^{j\pi(ux+vy)}$ • |

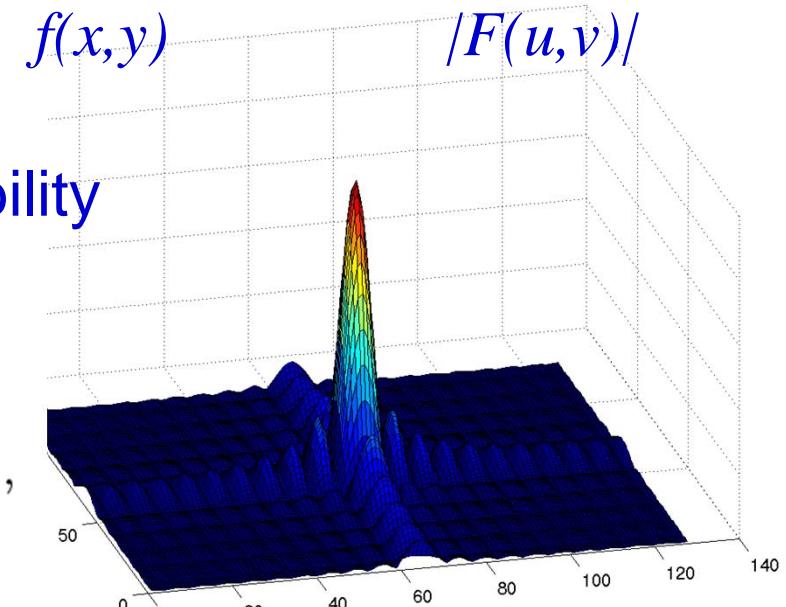

Some important Fourier Transform Pairs

FT pair example 1

rectangle centred at origin
with sides of length X and Y

$$\begin{aligned}
 F(u, v) &= \int \int f(x, y) e^{-j2\pi(ux+vy)} dx dy, \\
 &= \int_{-X/2}^{X/2} e^{-j2\pi ux} dx \int_{-Y/2}^{Y/2} e^{-j2\pi vy} dy, \quad \text{separability} \\
 &= \left[\frac{e^{-j2\pi ux}}{-j2\pi u} \right]_{-X/2}^{X/2} \left[\frac{e^{-j2\pi vy}}{-j2\pi v} \right]_{-Y/2}^{Y/2}, \\
 &= \frac{1}{-j2\pi u} [e^{-juX} - e^{juX}] \frac{1}{-j2\pi v} [e^{-jvY} - e^{jvY}], \\
 &= XY \left[\frac{\sin(\pi Xu)}{\pi Xu} \right] \left[\frac{\sin(2\pi Yv)}{\pi Yv} \right] \\
 &= XY \operatorname{sinc}(\pi Xu) \operatorname{sinc}(\pi Yv).
 \end{aligned}$$

$|F(u, v)|$

FT pair example 2

Gaussian centred on origin

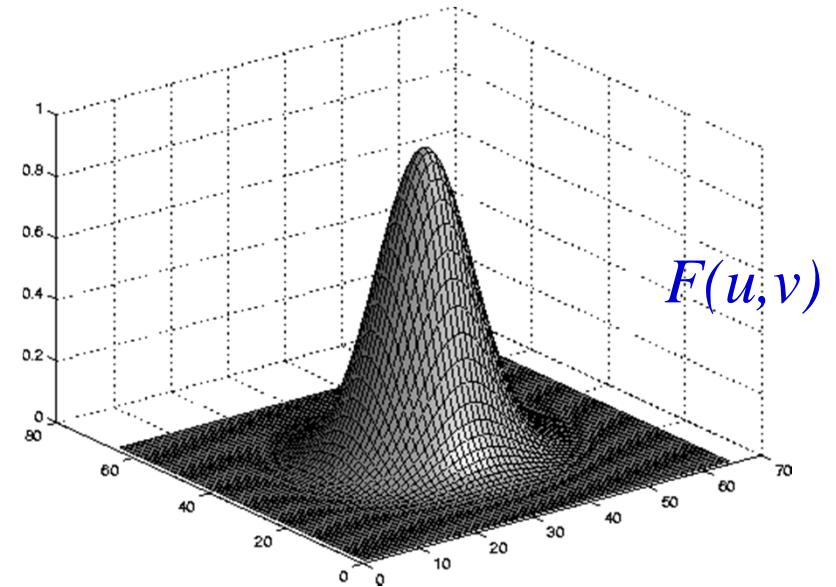

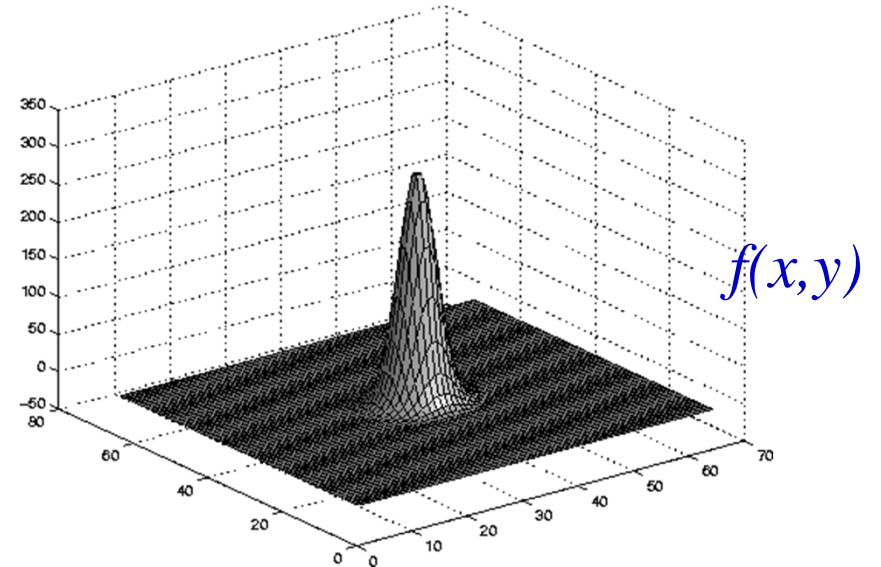

$$f(r) = \frac{1}{2\pi\sigma^2} e^{-r^2/2\sigma^2}$$

where $r^2 = x^2 + y^2$.

$$F(u, v) = F(\rho) = e^{-2\pi^2\rho^2\sigma^2}$$

where $\rho^2 = u^2 + v^2$.

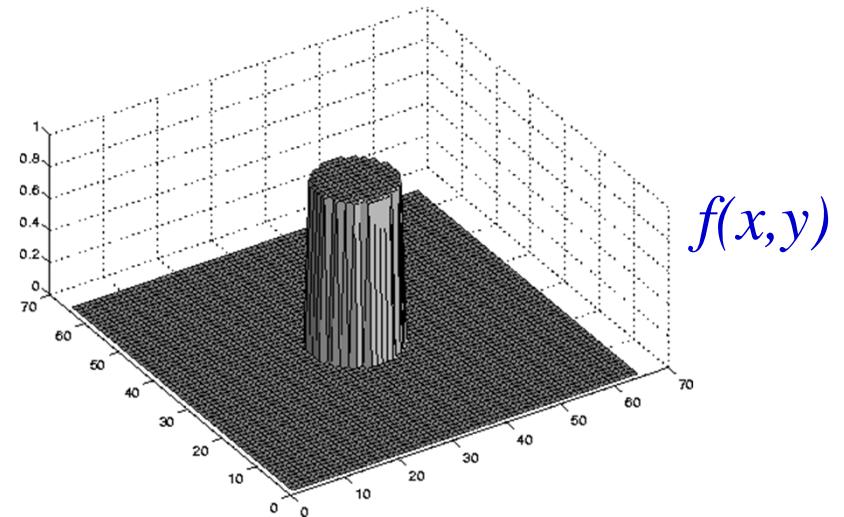

- FT of a Gaussian is a Gaussian
- Note inverse scale relation

FT pair example 3

Circular disk unit height and
radius a centred on origin

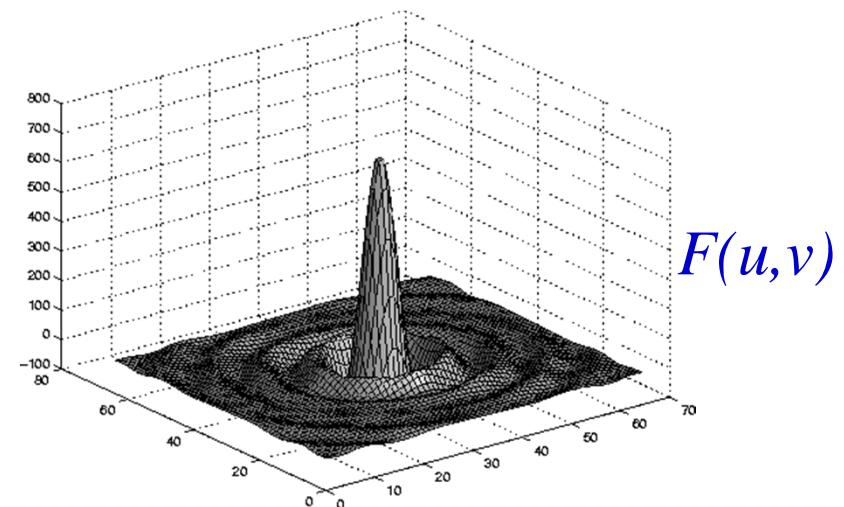

$$f(x, y) = \begin{cases} 1, & |r| < a, \\ 0, & |r| \geq a. \end{cases}$$

$$F(u, v) = F(\rho) = aJ_1(\pi a \rho)/\rho$$

where $J_1(x)$ is a Bessel function.

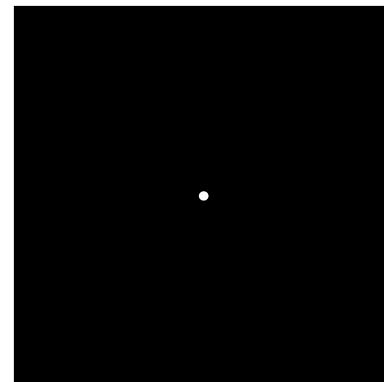

- rotational symmetry
- a '2D' version of a sinc

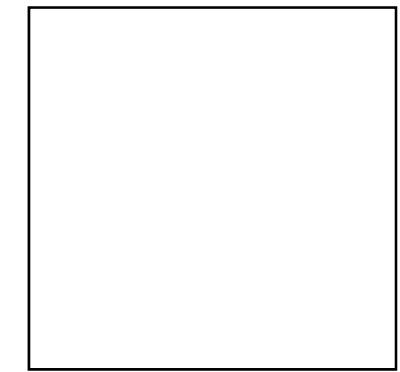

FT pairs example 4

$$f(x, y) = \delta(x, y) = \delta(x)\delta(y)$$

$$\begin{aligned} F(u, v) &= \int \int \delta(x, y) e^{-j2\pi(ux+vy)} dx dy \\ &= 1 \end{aligned}$$

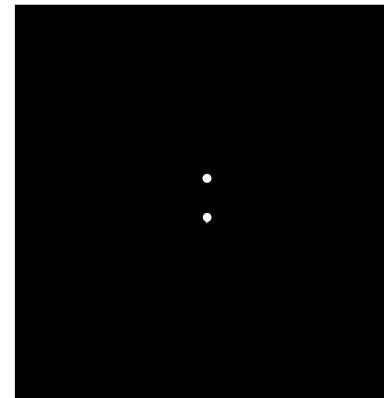

$f(x, y)$

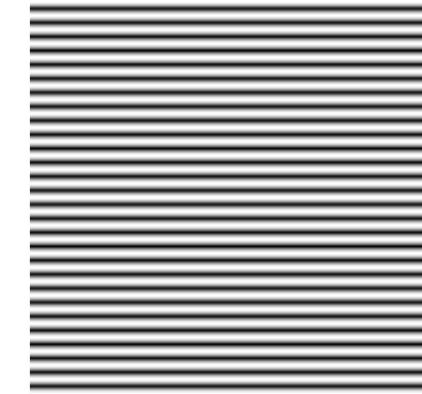

$F(u, v)$

$$f(x, y) = \frac{1}{2} (\delta(x, y - a) + \delta(x, y + a))$$

⋮

$$\begin{aligned} F(u, v) &= \frac{1}{2} \int \int (\delta(x, y - a) + \delta(x, y + a)) e^{-j2\pi(ux+vy)} dx dy \\ &= \frac{1}{2} (e^{-j2\pi av} + e^{j2\pi av}) = \cos 2\pi av \end{aligned}$$

Summary

The spatial function $f(x, y)$

$$f(x, y) = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} F(u, v) e^{j2\pi(ux+vy)} du dv$$

is decomposed into a weighted sum of 2D orthogonal basis functions in a similar manner to decomposing a vector onto a basis using scalar products.

$f(x, y)$

$$= \alpha \begin{array}{c} \text{Vertical stripes} \\ \text{Basis function} \end{array} + \beta \begin{array}{c} \text{Horizontal stripes} \\ \text{Basis function} \end{array} + \gamma \begin{array}{c} \text{Diagonal stripes} \\ \text{Basis function} \end{array} + \dots$$

Example: action of filters on a real image

phase

magnitude

phase

Transformations

As in the 1D case FTs have the following properties

- Linearity

$$\alpha f(x, y) + \beta g(x, y) \Leftrightarrow \alpha F(u, v) + \beta G(u, v).$$

- Similarity

$$f(ax, by) \Leftrightarrow \frac{1}{ab} F\left(\frac{u}{a}, \frac{v}{b}\right).$$

This applies, for example, when an image is scaled

- Shift

$$f(x - a, y - b) \Leftrightarrow e^{j2\pi(au+bv)} F(u, v)$$

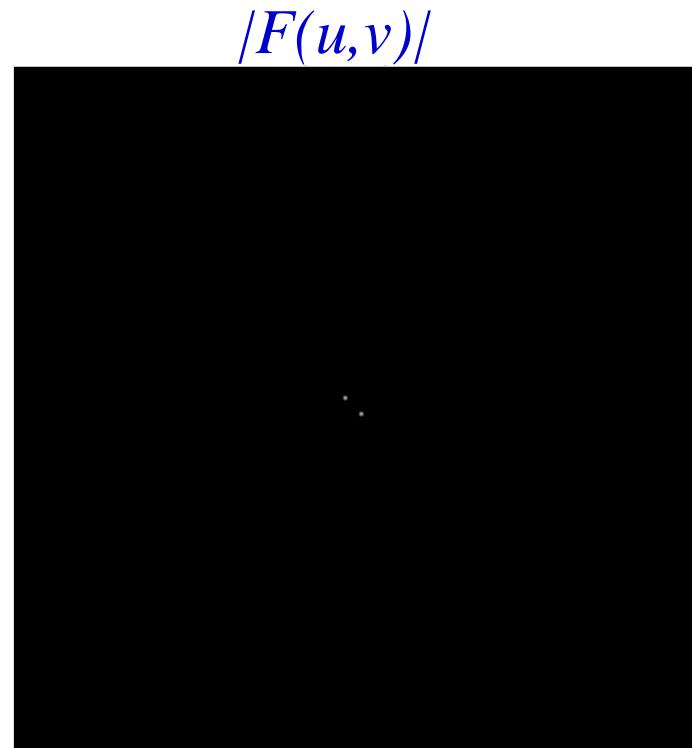

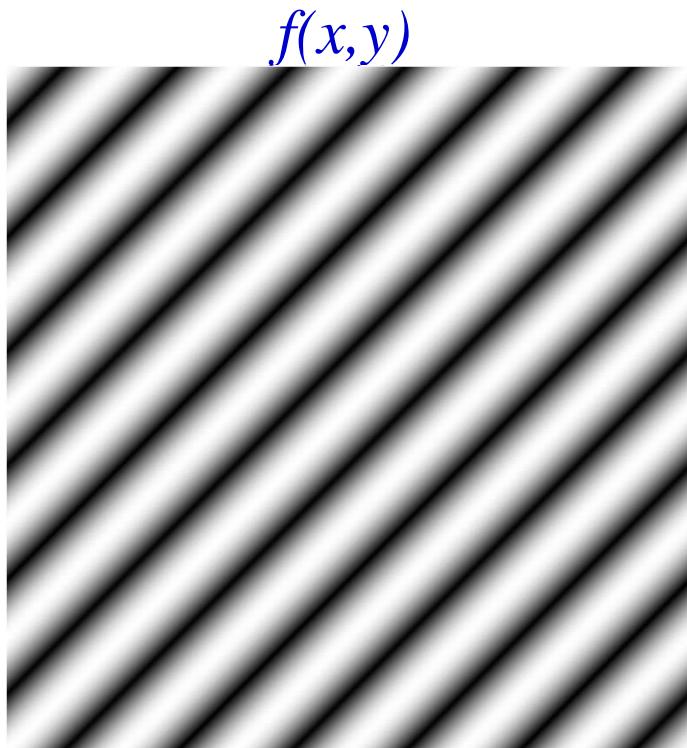

This might apply, for example, if an object moved.

In 2D can also rotate, shear etc

Under an affine transformation: $\mathbf{x} \rightarrow A\mathbf{x}$ $\mathbf{u} \rightarrow A^{-T}\mathbf{u}$

Example

How does $F(u,v)$ transform if $f(x,y)$ is rotated by 45 degrees?

If $A = R$ then $A^{-T} = R$.

i.e. FT undergoes the same rotation.

The convolution theorem

Filtering vs convolution in 1D

$$g(x) = \sum_i f(x + i)h(i)$$

filtering $f(x)$ with $h(x)$

$$f(x) \quad \boxed{100 | 200 | 100 | 200 | 90 | 80 | 80 | 100 | 100}$$

$$h(x) \quad \boxed{1/4 | 1/2 | 1/4}$$

molecule/template/kernel

$$g(x) \quad \boxed{| 150 | \quad | \quad | \quad | \quad | \quad | \quad |}$$

$$g(x) = \int f(u)h(x - u) du \quad \text{convolution of } f(x) \text{ and } h(x)$$

$$\begin{aligned} &= \int f(x + u')h(-u') du' \\ &= \sum_i f(x + i)h(-i) \end{aligned} \quad \text{after change of variable } u' = u - x$$

- note negative sign (which is a reflection in x) in convolution

- $h(x)$ is often symmetric (even/odd), and then (e.g. for even)

$$g(x) = \sum_i f(x + i)h(i)$$

Filtering vs convolution in 2D

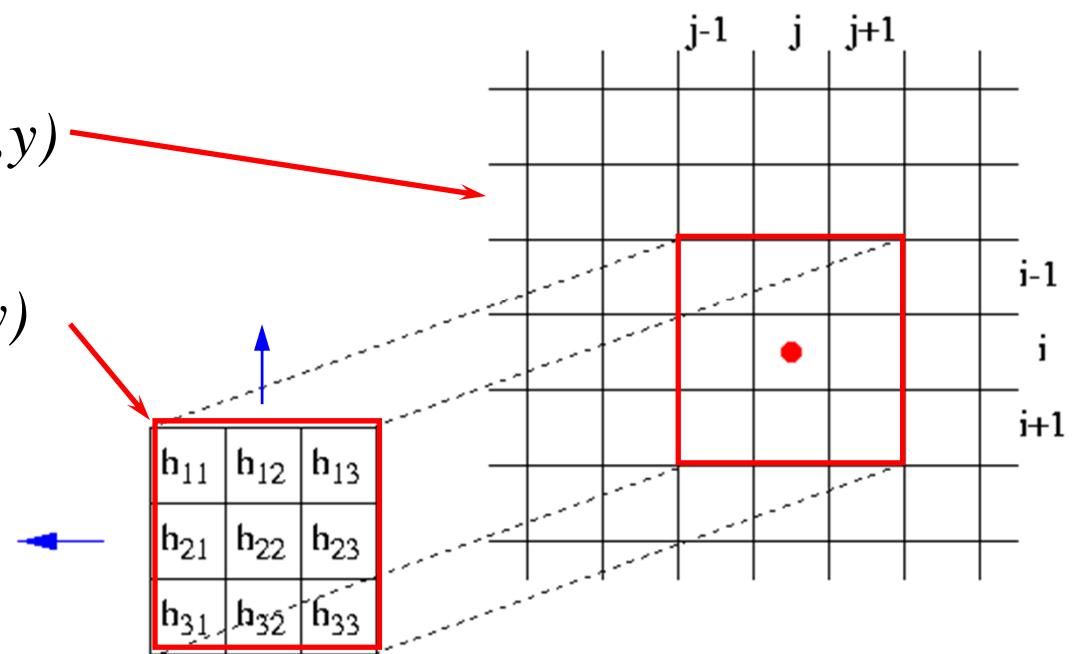

convolution

$$\begin{aligned} g(x, y) &= h(x, y) * f(x, y) = f(x, y) * h(x, y) \\ &= \int \int f(u, v)h(x - u, y - v) du dv \end{aligned}$$

filtering

image $f(x, y)$

filter / kernel $h(x, y)$

$$\begin{aligned} g(x, y) = & h_{11} f(i - 1, j - 1) + h_{12} f(i - 1, j) + h_{13} f(i - 1, j + 1) + \\ & h_{21} f(i, j - 1) + h_{22} f(i, j) + h_{23} f(i, j + 1) + \\ & h_{31} f(i + 1, j - 1) + h_{32} f(i + 1, j) + h_{33} f(i + 1, j + 1) \end{aligned}$$

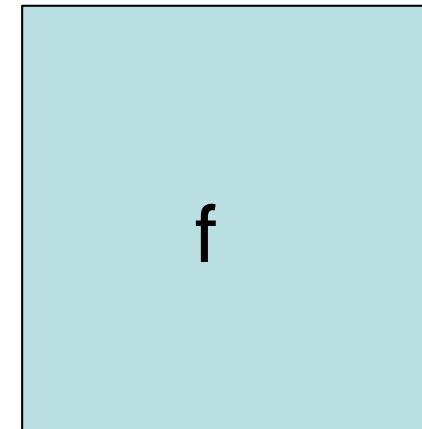

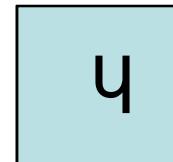

for convolution, reflect filter in x and y axes

Convolution

- Convolution:
 - Flip the filter in both dimensions (bottom to top, right to left)

$$g[i, j] = \sum_{u=-k}^k \sum_{v=-k}^k h[u, v] f[i - u, j - v]$$

convolution with h

Filtering vs convolution in 2D in Matlab

2D filtering

- `g=filter2(h,f);`

`f=image`

`h=filter`

$$g[m,n] = \sum_{k,l} h[k,l] f[m+k, n+l]$$

2D convolution

- `g=conv2(h,f);`

$$g[m,n] = \sum_{k,l} h[k,l] f[m-k, n-l]$$

Convolution theorem

$$f(x, y) * h(x, y) \Leftrightarrow F(u, v)H(u, v)$$

Space convolution = frequency multiplication

In words: the Fourier transform of the convolution of two functions is the product of their individual Fourier transforms

Proof: exercise

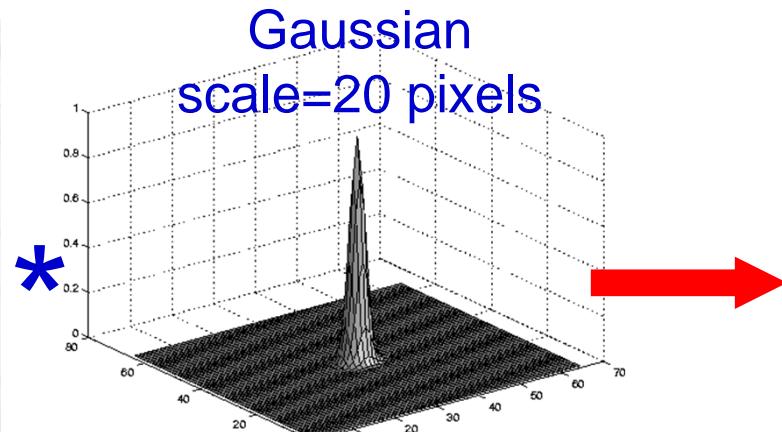

Why is this so important?

Because linear filtering operations can be carried out by simple multiplications in the Fourier domain

The importance of the convolution theorem

It establishes the link between operations in the frequency domain and the action of linear spatial filters

Example smooth an image with a Gaussian spatial filter

1. Compute FT of image and FT of Gaussian
2. Multiply FT's
3. Compute inverse FT of the result.

$$f(x, y) * g(x, y) \Leftrightarrow F(u, v)G(u, v)$$

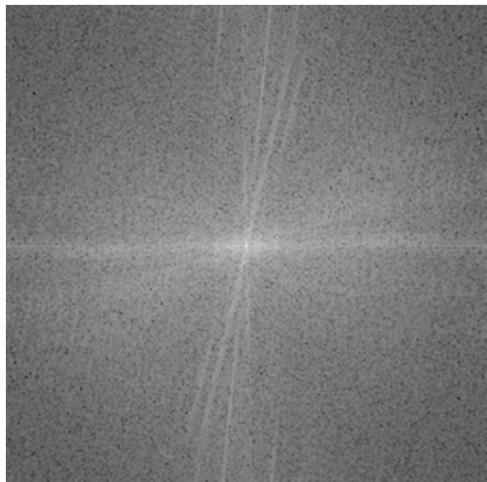

$f(x,y)$

Gaussian
scale=3 pixels

Fourier transform

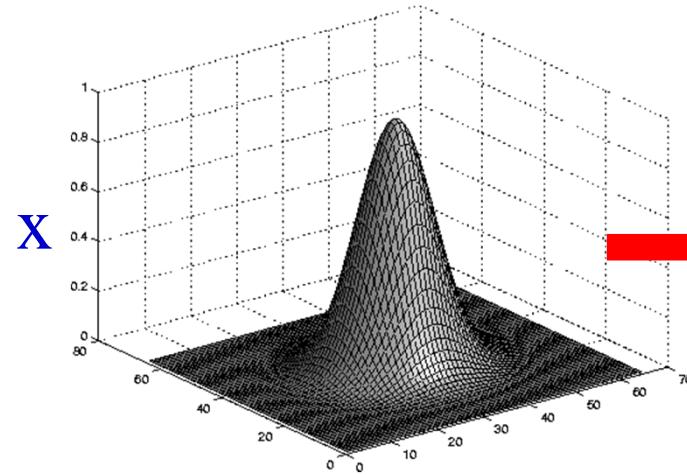

$|F(u,v)|$

$g(x,y)$

Inverse Fourier
transform

$|G(u,v)|$

$f(x,y)$

Gaussian scale=3 pixels

*

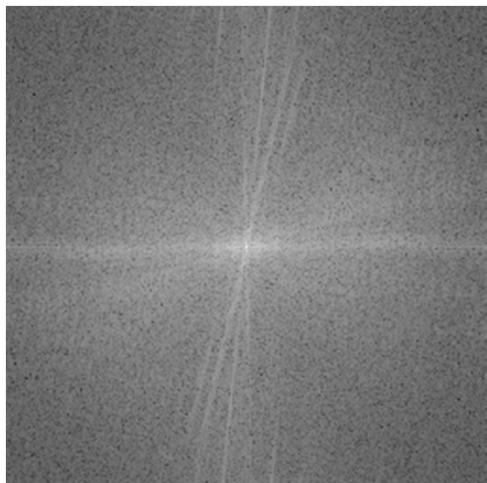

$g(x,y)$

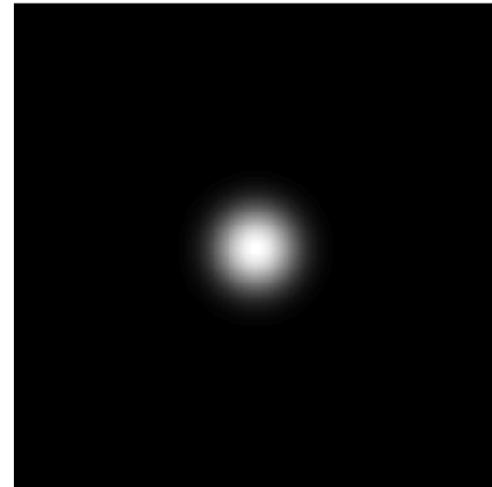

Fourier transform

↓

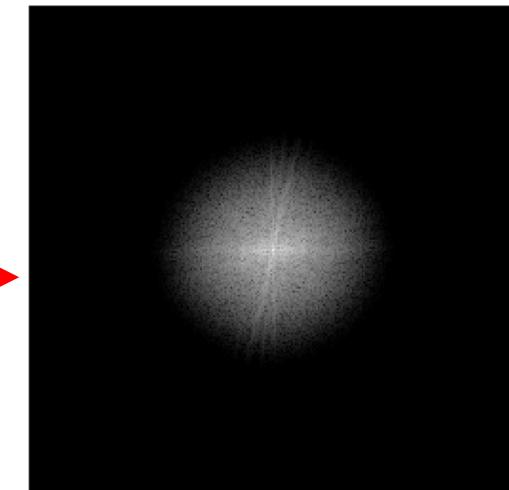

X

Inverse Fourier
transform

↑

$|F(u,v)|$

$|G(u,v)|$

There are two equivalent ways of carrying out linear spatial filtering operations:

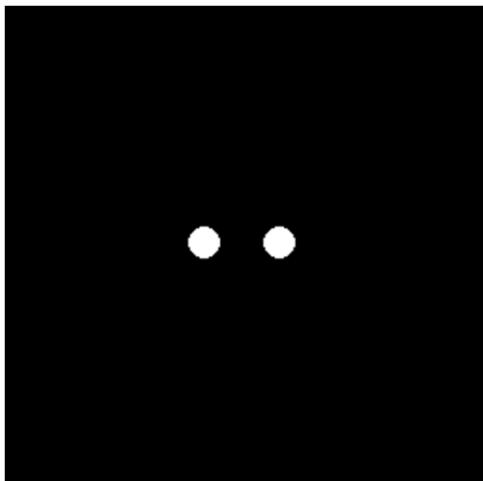

1. Spatial domain: convolution with a spatial operator
2. Frequency domain: multiply FT of signal and filter, and compute inverse FT of product

Why choose one over the other ?

- The filter may be simpler to specify or compute in one of the domains
- Computational cost

Exercise

What is the FT of ...

?

2 small disks

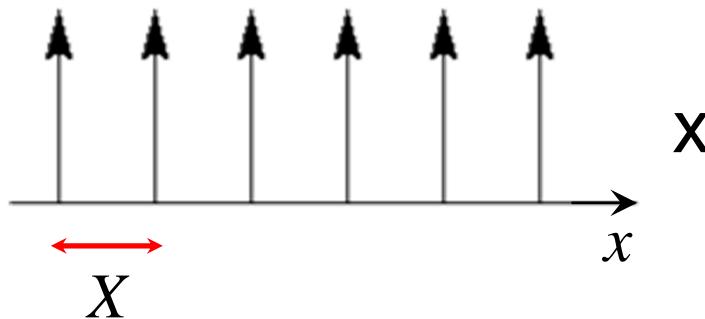

The sampling theorem

Discrete Images - Sampling

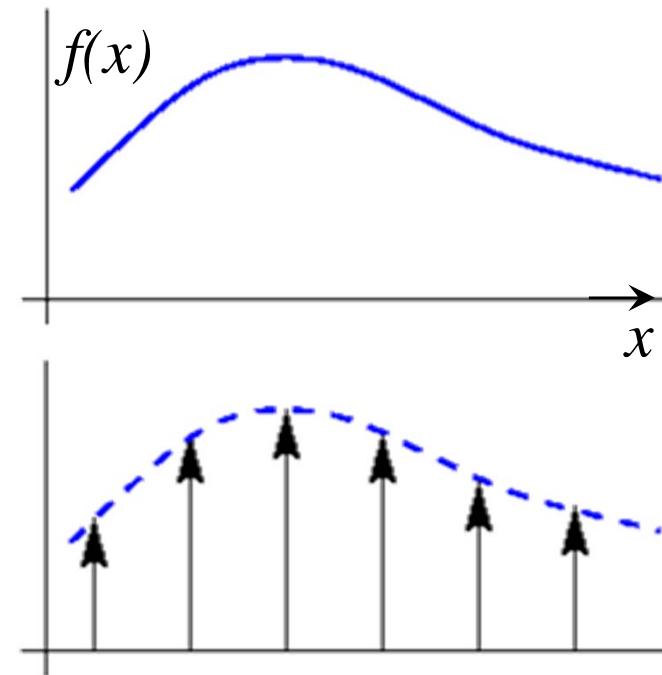

In 1D model the image as a set of point samples obtained by multiplying $f(x)$ by the **comb** function

$$\text{comb}(x) = \sum_{n=-\infty}^{\infty} \delta(x - nX)$$

an infinite set of delta functions spaced by X .

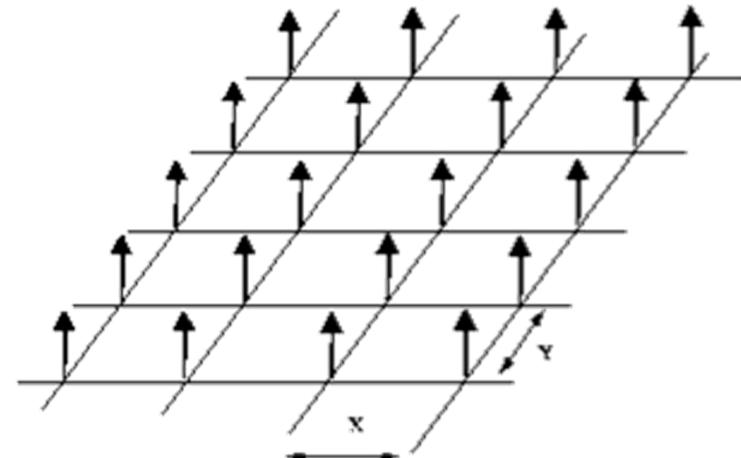

$$f_s(x) = \sum_{n=-\infty}^{\infty} \delta(x - nX) f(x)$$

In 2D the equivalent of a comb is a **bed-of-nails** function

$$\sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \delta(x - nX) \delta(y - mY)$$

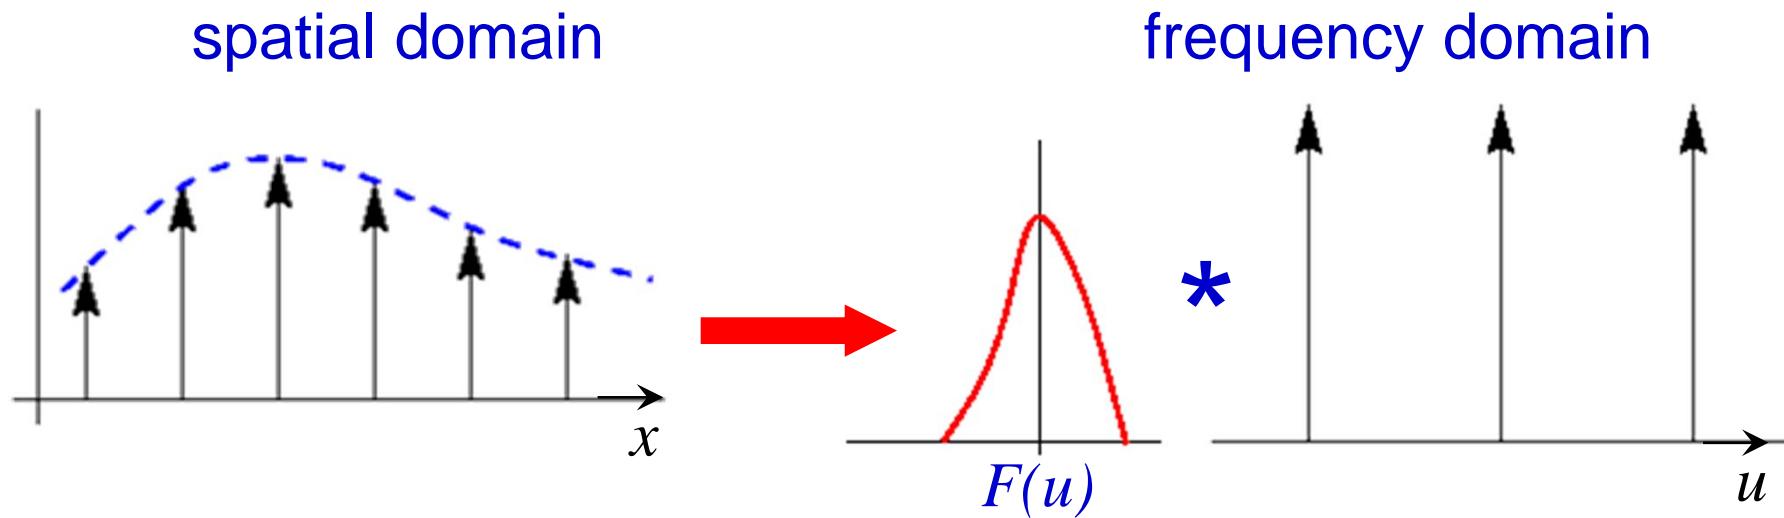

Fourier transform pairs

$$\sum_{n=-\infty}^{\infty} \delta(x - nX) \leftrightarrow \frac{1}{X} \sum_{n=-\infty}^{\infty} \delta(u - n/X)$$

$$\sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \delta(x - nX) \delta(y - mY) \leftrightarrow \frac{1}{XY} \sum_{n=-\infty}^{\infty} \delta(u - n/X) \sum_{m=-\infty}^{\infty} \delta(v - m/Y)$$

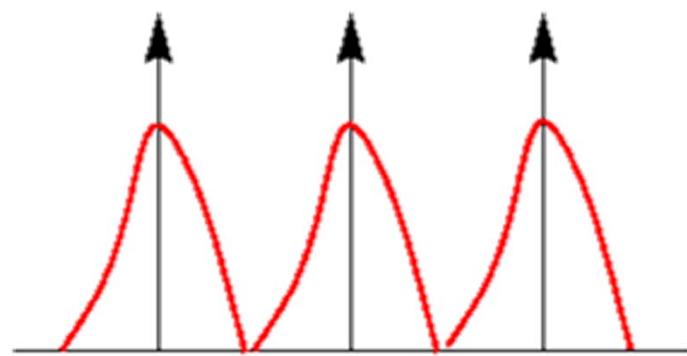

Sampling Theorem in 1D

$$f_s(x) = \sum_{n=-\infty}^{\infty} \delta(x - nX) f(x)$$

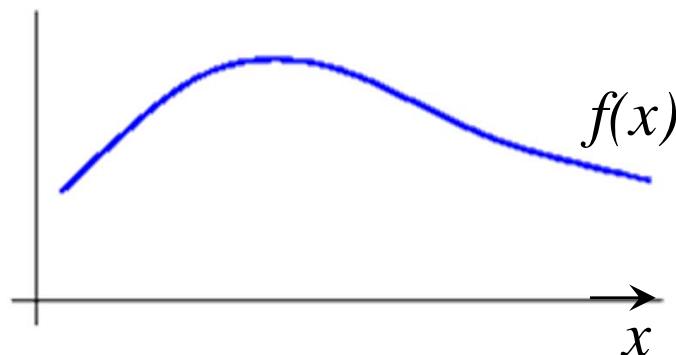

$$= \sum_{n=-\infty}^{\infty} f(nX) \delta(x - nX)$$

$$F_s(u) = \frac{1}{X} \sum_{n=-\infty}^{\infty} \delta(u - n/X) * F(u) = \frac{1}{X} \sum_{n=-\infty}^{\infty} F(u - n/X)$$

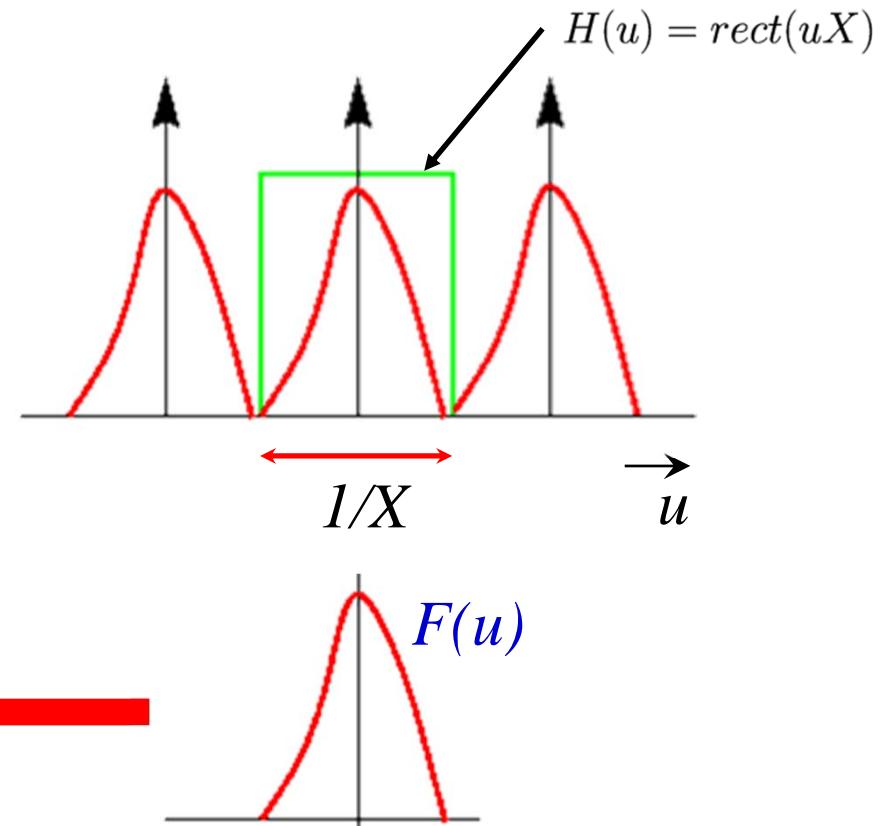

replicated copies of $F(u)$

Apply a box filter

$$\begin{aligned}f(x) &= \sum_{n=-\infty}^{\infty} f(nX) \delta(x - nX) * \text{sinc} \frac{\pi x}{X} \\&= \sum_{n=-\infty}^{\infty} f(nX) \text{sinc} \frac{\pi}{X} (x - nX)\end{aligned}$$

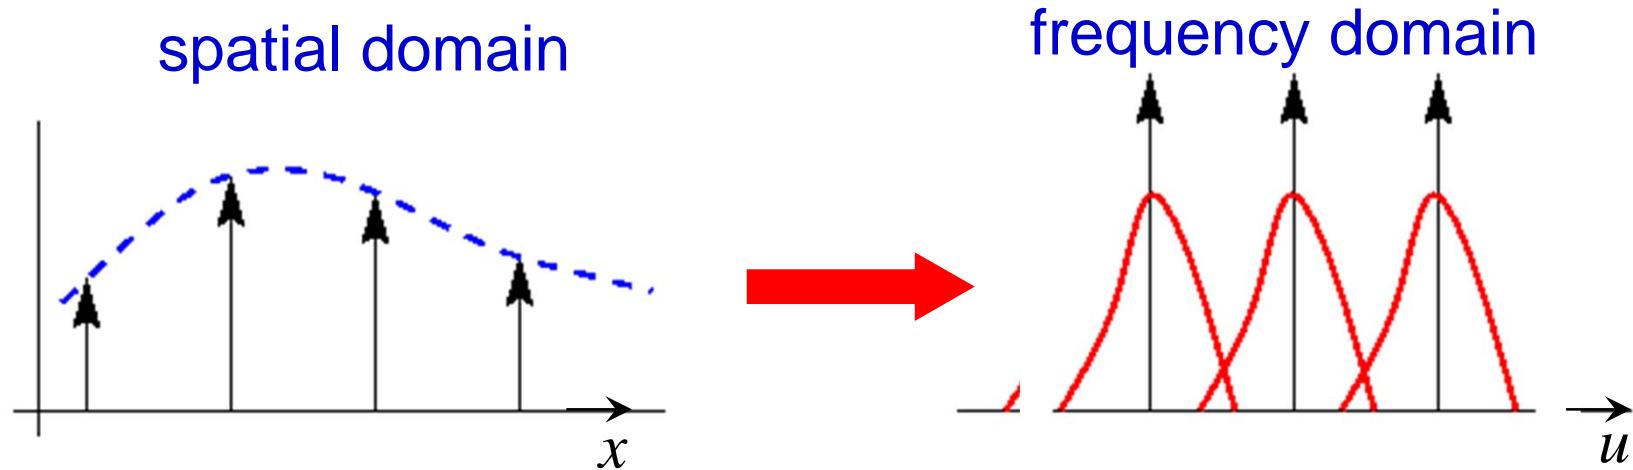

$$F(u) = F_s(u)H(u)$$

The original continuous function $f(x)$ is completely recovered from the samples provided the sampling frequency ($1/X$) exceeds twice the greatest frequency of the band-limited signal. (Nyquist sampling limit)

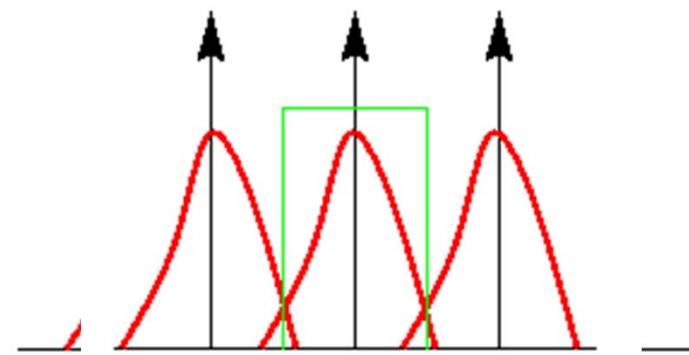

The Sampling Theorem and Aliasing

if sampling frequency is reduced ...

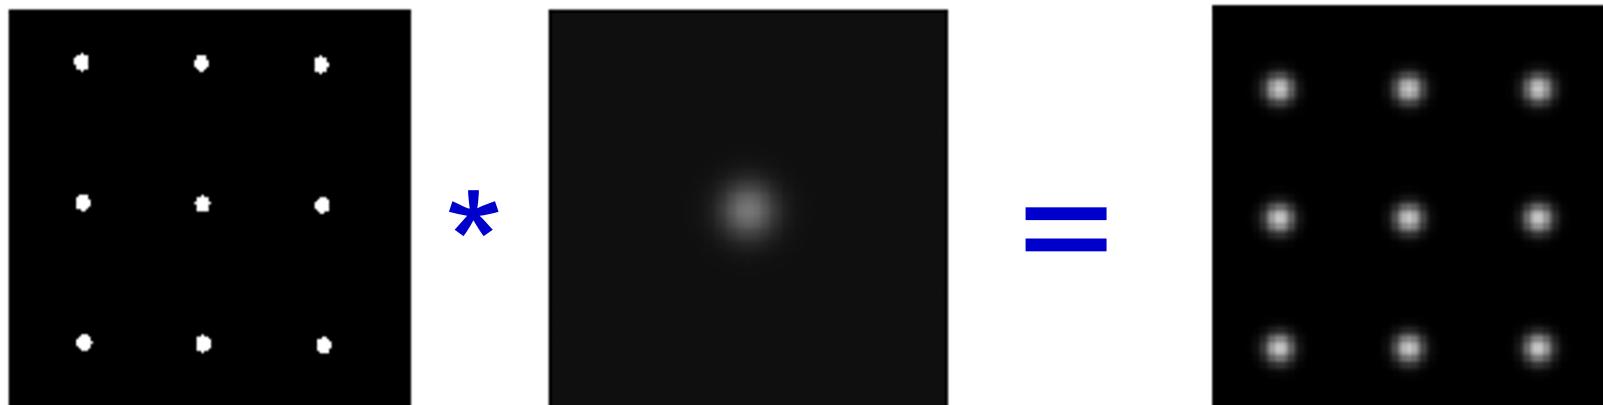

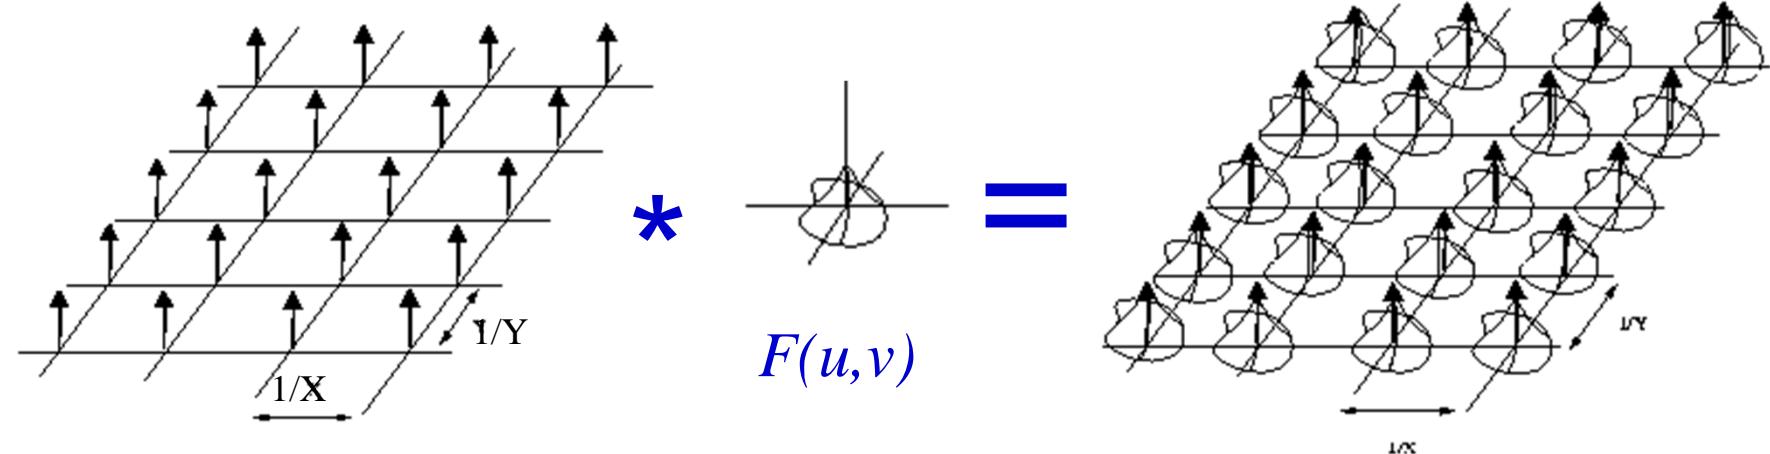

Frequencies above the Nyquist limit are 'folded back' corrupting the signal in the acceptable range.

The information in these frequencies is not correctly reconstructed.

Sampling Theorem in 2D

frequency domain

$$H(u, v) = \text{rect}(uX)\text{rect}(vY)$$

$$f(x, y) = \sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} f(nX, mY) \text{sinc} \frac{\pi}{X}(x - nX) \text{sinc} \frac{\pi}{Y}(y - mY)$$

The sampling theorem in 2D

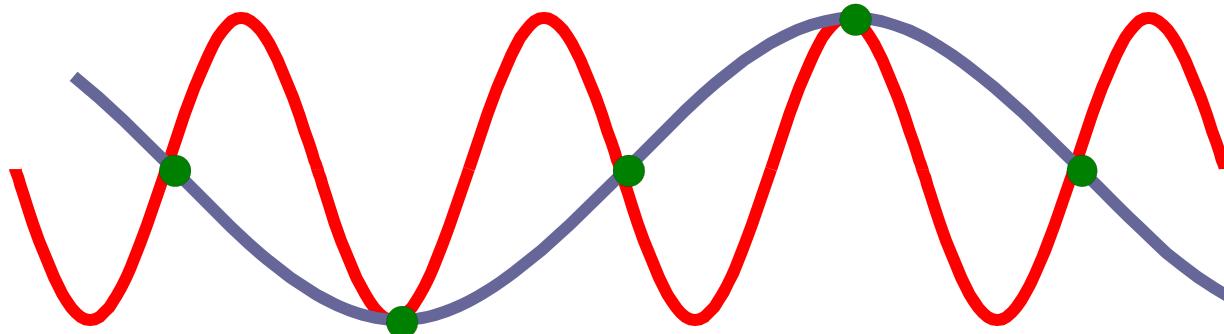

If the Fourier transform of a function $f(x,y)$ is zero for all frequencies beyond u_b and v_b , i.e. if the Fourier transform is ***band-limited***, then the continuous function $f(x,y)$ can be completely reconstructed from its samples as long as the sampling distances w and h along the x and y directions

are such that $w \leq \frac{1}{2u_b}$ and $h \leq \frac{1}{2v_b}$

Aliasing

Aliasing : 1D example

If the signal has frequencies above the Nyquist limit ...

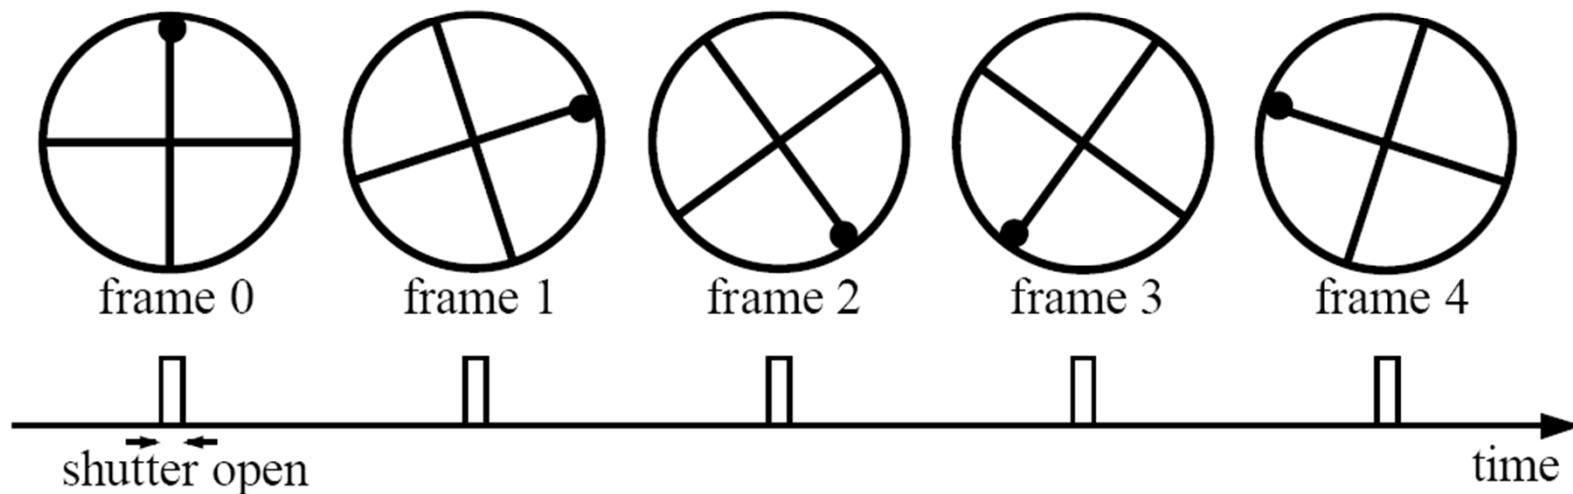

Insufficient samples to distinguish the high and low frequency
aliasing: signals “travelling in disguise” as other frequencies

Aliasing in video

Imagine a spoked wheel moving to the right (rotating clockwise).

Mark wheel with dot so we can see what's happening.

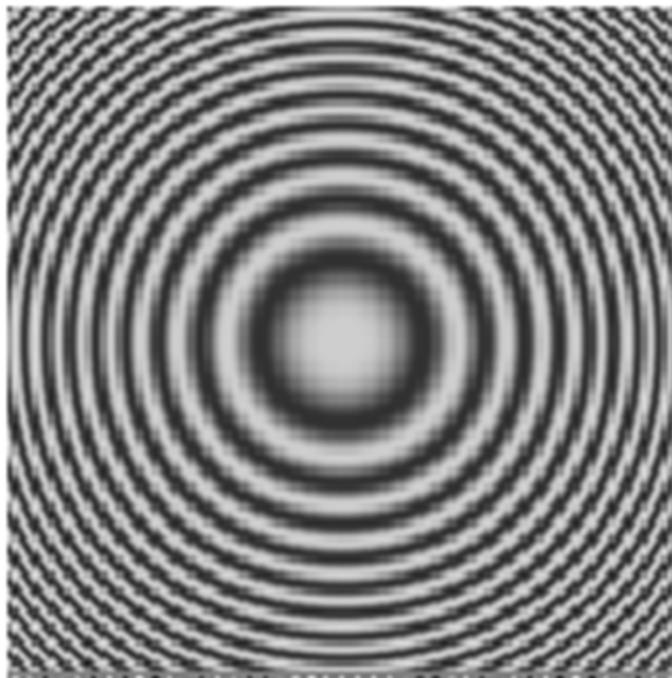

If camera shutter is only open for a fraction of a frame time (frame time = 1/30 sec. for video, 1/24 sec. for film):

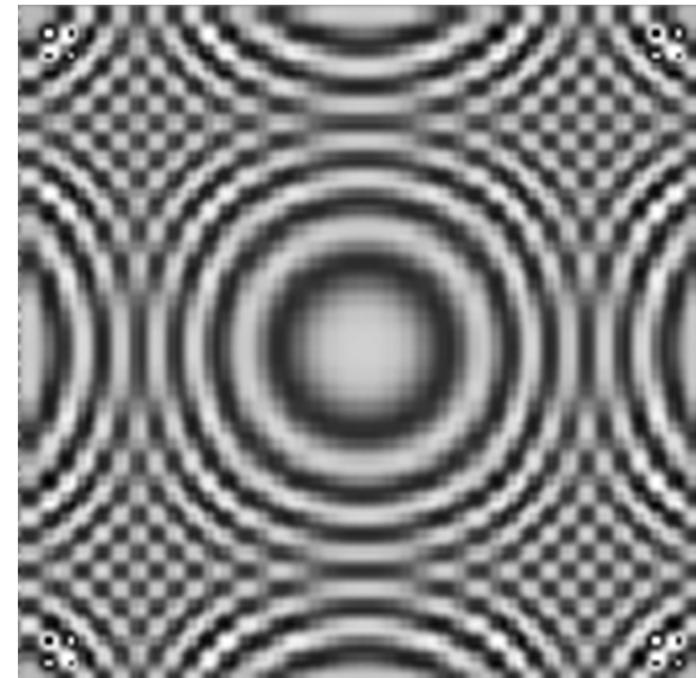

Without dot, wheel appears to be rotating slowly backwards!
(counterclockwise)

Aliasing in 2D – under sampling example

original

reconstruction

signal has frequencies
above Nyquist limit

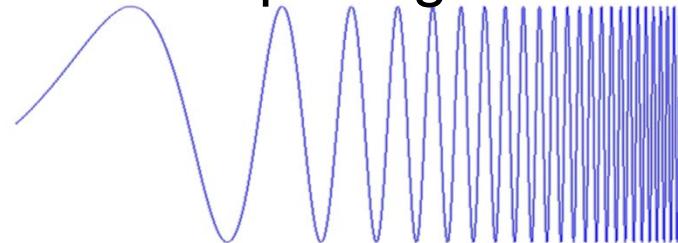

Aliasing in images

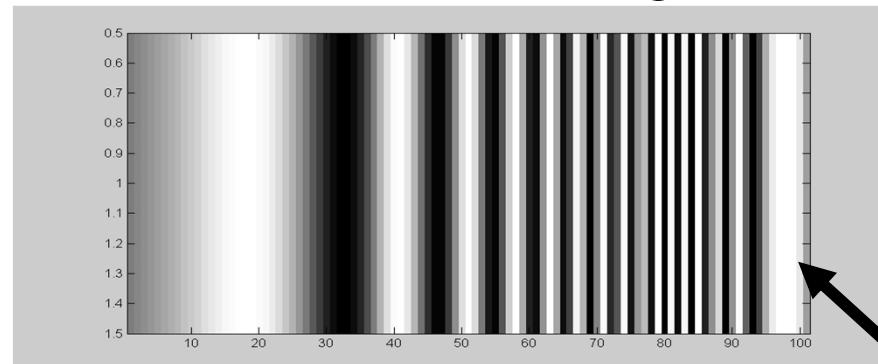

Disintegrating textures

What's happening?

Input signal:

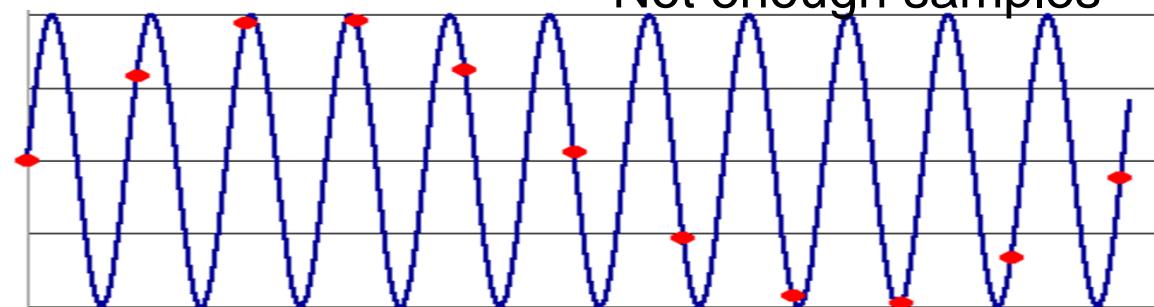

Plot as image:

```
x = 0:.05:5; imagesc(sin((2.^x).*x))
```

Aliasing
Not enough samples

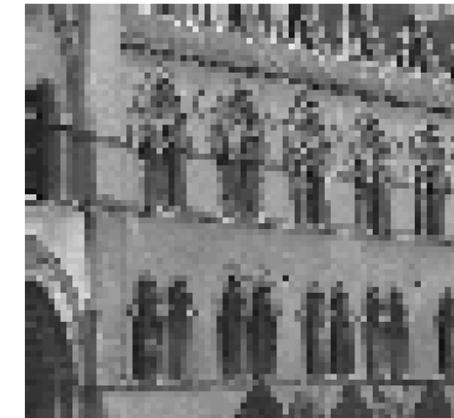

Anti-Aliasing

- Increase sampling frequency
 - e.g. in graphics rendering cast 4 rays per pixel
- Reduce maximum frequency to below Nyquist limit
 - e.g. low pass filter before sampling

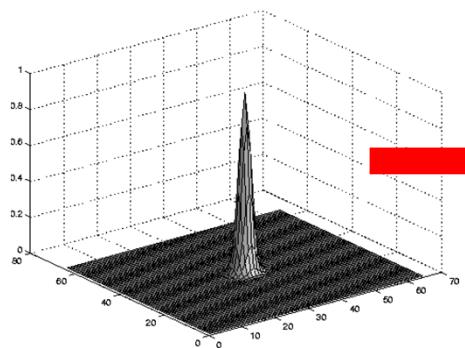

Example

down sample by
factor of 4

convolve with
Gaussian

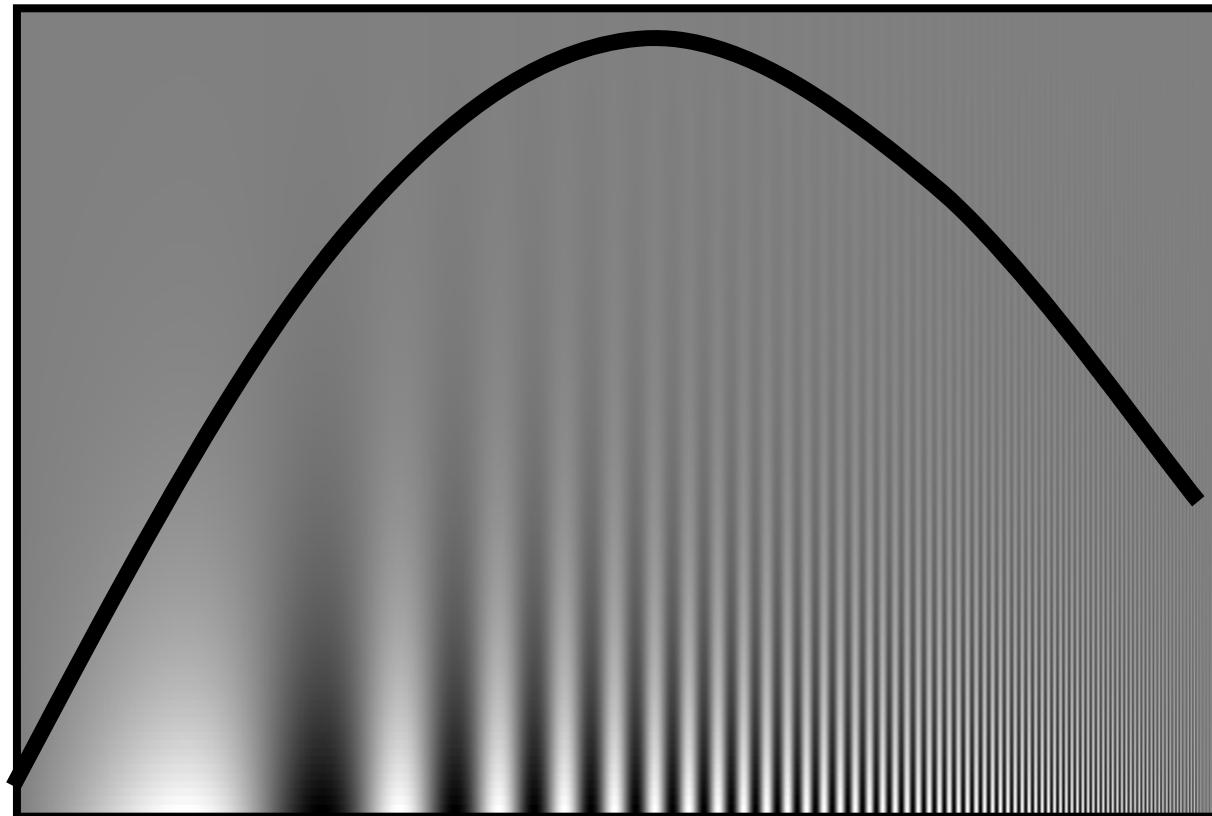

down sample by
factor of 4

4 x zoom
